

# Java Crash Course Part III

Institut für Wirtschaftsinformatik  
HU-Berlin WS 2004

Sebastian Kolbe  
skolbe@wiwi.hu-berlin.de

# *What you should know so far*

- ◆ How to compile and start a Java application
- ◆ Java-Syntax and concepts
  - ◆ Variables
  - ◆ Operators
  - ◆ Control structures (if-then-else, different loops)
  - ◆ Conventions in Java  
(capital letter for classes, lowercase letter for methods,...)
  - ◆ Modifiers for classes, variables and methods  
(public, protected, private, static)
- ◆ Classes and objects
  - ◆ General idea
  - ◆ Java Syntax

# *Predefined functions in Java*

- ◆ Java brings a huge database of predefined functions in several libraries
- ◆ Hierarchical organisation

```
java.lang.System.out.println();
```

- ◆ Classes with: `java.[..]` belong to the standard Java SDK package
- ◆ Using other packages as `java.lang` requires import of package: 

```
import java.util.*;
```
- ◆ See Java-Documentation  
<http://coltrane.wiwi.hu-berlin.de/lehre/2004w/isi/javaDoku/api/index.html>

# *Inheritance*

- ◆ A subclass inherits behavior (variables and methods) from its ancestors
- ◆ From the subclass point of view the ancestors are called superclasses
- ◆ Advantages:
  - ◆ reusing of code
  - ◆ cleaner design
- ◆ Disadvantages:
  - ◆ sometimes more code to write
  - ◆ complex structures are hardly to understand  
-> **USE COMMENTS & document your program**

# *A more complex example*

Think about geometric figures...

They all have things in common...  
and other things uncommon

# Creating hierarchies

Define a “interface” and capabilities (generic)

`Geometric.java`

Implement more specific for a special kind of thing

`Rectangle.java`

Implement a certain geometric structure

`Parallelogram.java`

`Square.java`

`Circle.java`

Test your program

`GeomTest.java`
